Natural cements in European cultural heritage  
Les ciments naturels dans le patrimoine européen  
PARIS – 26/27-04-2012

## Introduction

- Previous lecture on the different facilities of production of Roman cement
- What can be the composition of these cements?
- How do they hydrate?

# 1/ Background

- Calcination of marlstone to produce cement is a complex process
- Involving the raw materials (minerals) and the kiln parameters (residence time, max. temp., quenching...)

Marlstone Quarry  
(Austria)

Crushed  
Marlstones

Shaft kiln

(~ 800-1000°C)

“Cement stones” (clinker)

Grinding

# 1/ Background

- Calcination of marlstone to produce cement is a complex process
- Involving the raw materials (minerals) and the kiln parameters (residence time, max. temp., quenching...)

Marlstone Quarry  
(Austria)

Crushed  
Marlstones

## Limestone + 25-35%wt clay minerals

- Calcite  $\text{CaCO}_3$ / dolomite  $\text{CaMg}(\text{CO}_3)_2$
- Quartz  $\text{SiO}_2$
- Clay materials  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$
- If iron sulfur minerals ( $\text{FeS}_2$ ,  $\text{FeS}\dots$ )  $\rightarrow \text{SO}_3$

# 1/ Background

## Calcination (1/3)

From 650°C,  $\text{CaCO}_3$  will release  $\text{CaO}$  and  $\text{CO}_2$

$\text{CaO}$

$\text{Al}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$   
and if  $T > 1000^\circ\text{C}$

$\text{Al}_2\text{O}_3$

a bit of crystalline  $\text{C}_3\text{A}$  and  $\text{C}_4\text{AF}$

a lot of amorphous  $\text{CaO} - \text{Al}_2\text{O}_3$

React very quickly with water  $\rightarrow$  flash setting (no workability)

# 1/ Background

## Calcination (2/3)

From 650°C,  $\text{CaCO}_3$  will release  $\text{CaO}$  and  $\text{CO}_2$

**$2\text{CaO}\cdot\text{SiO}_2$**   
( $\text{C}_2\text{S}$ , under two crystal structures  
 $\alpha'$  and  $\beta$ , so-called belite)

**$2\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot\text{SiO}_2$**   
( $\text{C}_2\text{AS}$ , gehlenite)

**carbonated  $\text{C}_2\text{S}$**

**Reactivity with water:**

Carbonated  $\text{C}_2\text{S}$  <  $\text{C}_2\text{AS}$  <  $\beta\text{-C}_2\text{S}$  <  $\alpha'\text{-C}_2\text{S}$

# 1/ Background

## Calcination (3/3)

Sometimes **under-burnt** materials .....

Remaining  
raw minerals

Cement phases

..... **burnt** and **over-burnt** part of the calcined stones  
are ground all together

# 1/ Background

In the real life

Shut up  
!

$\alpha'$  or  $\beta - C_2S$  ?!

Image: Demonstration Site, Chateau Valère, Sion, CH

## 2/ Composition of Roman cements

### 4 cements

- Cement from a historic Austrian marl Lilienfeld – reference cement fired under **laboratory conditions**
- **Semi-Industrial** MBM-Gartenau, Poland – pilot rotary kiln
- **Industrial** Vicat Prompt, France – shaft kilns
- **Industrial** Wittersdorfer & Peggauer, Austria - a rotary kiln

# 2/ Composition of Roman cements

## XRD crystalline composition

	Lilienfeld ~860°C	MBM-Gartenau 870 → 970°C	Vicat Prompt 600→1200°C (*)	Wittersdofer & Peggauer 800→1000°C
<b><u>Total belite</u></b> $\alpha' + \beta\text{-C}_2\text{S}$	<b>48</b>	<b>47</b>	<b>44</b> <b>But C<sub>3</sub>S (also)</b>	<b>23</b>
<b><u>Ratio</u></b> $\alpha' / \beta \text{ C}_2\text{S}$	<b>6</b>	<b>0.6</b>	<b>0.3</b>	<b>0.35</b>
<b><u>Carbonated</u></b> <b><u>C<sub>2</sub>S</u></b>	<b>6.9</b>	<b>16.5</b>	<b>15.2</b>	<b>7.1</b>
<b><u>Remaining</u></b> <b><u>raw materials</u></b> <b>(calcite,</b> <b>quartz, clay)</b>	<b>34.6</b>	<b>18.9</b>	<b>17.6</b>	<b>35.1</b>

(\*) Vicat cement differs because contains C<sub>3</sub>S and gypsum

## 2/ Composition of Roman cements

- Composition of cements produced in a traditional kiln
- Four samples from the same calcination batch

**Shaft kiln in Mauerbach, (Austria)**

# 2/ Composition of Roman cements

	1 Bottom core (939°C)	2 Bottom wall (859°C)	3 top core (1133°C)	4 top wall (841°C)
<b>Total belite</b> $\alpha' + \beta\text{-C}_2\text{S}$	54	35	72	34
<b>Ratio</b> $\alpha' / \beta \text{ C}_2\text{S}$	0.6	2.0	0.6	1.6
<b>Carbonated <math>\text{C}_2\text{S}</math></b>	6.1	17.7	5.7	10.3
<b>Remaining raw materials</b> (calcite quartz mica)	11.1	27.9	1.9	43.6

## 2/ Composition of Roman cements

### Summary

- A **wide range of crystalline** composition is obtained  
→ due to the raw materials, the calcination parameters...
- The  $\alpha'$ - $C_2S$  polymorphism dominates but the relative amount of  $\alpha'$ - $C_2S$  and  $\beta$ - $C_2S$  is changing with the calcination conditions  
→ Influence on the hydration and strength development
- The **carbonation of calcium silicate** can occur (depends on the type of kiln and local reduction conditions)  
→ Less  $C_2S$  is available for hydration

# 3/ Hydration of Roman cements

How do ...

... Roman  
cements ...

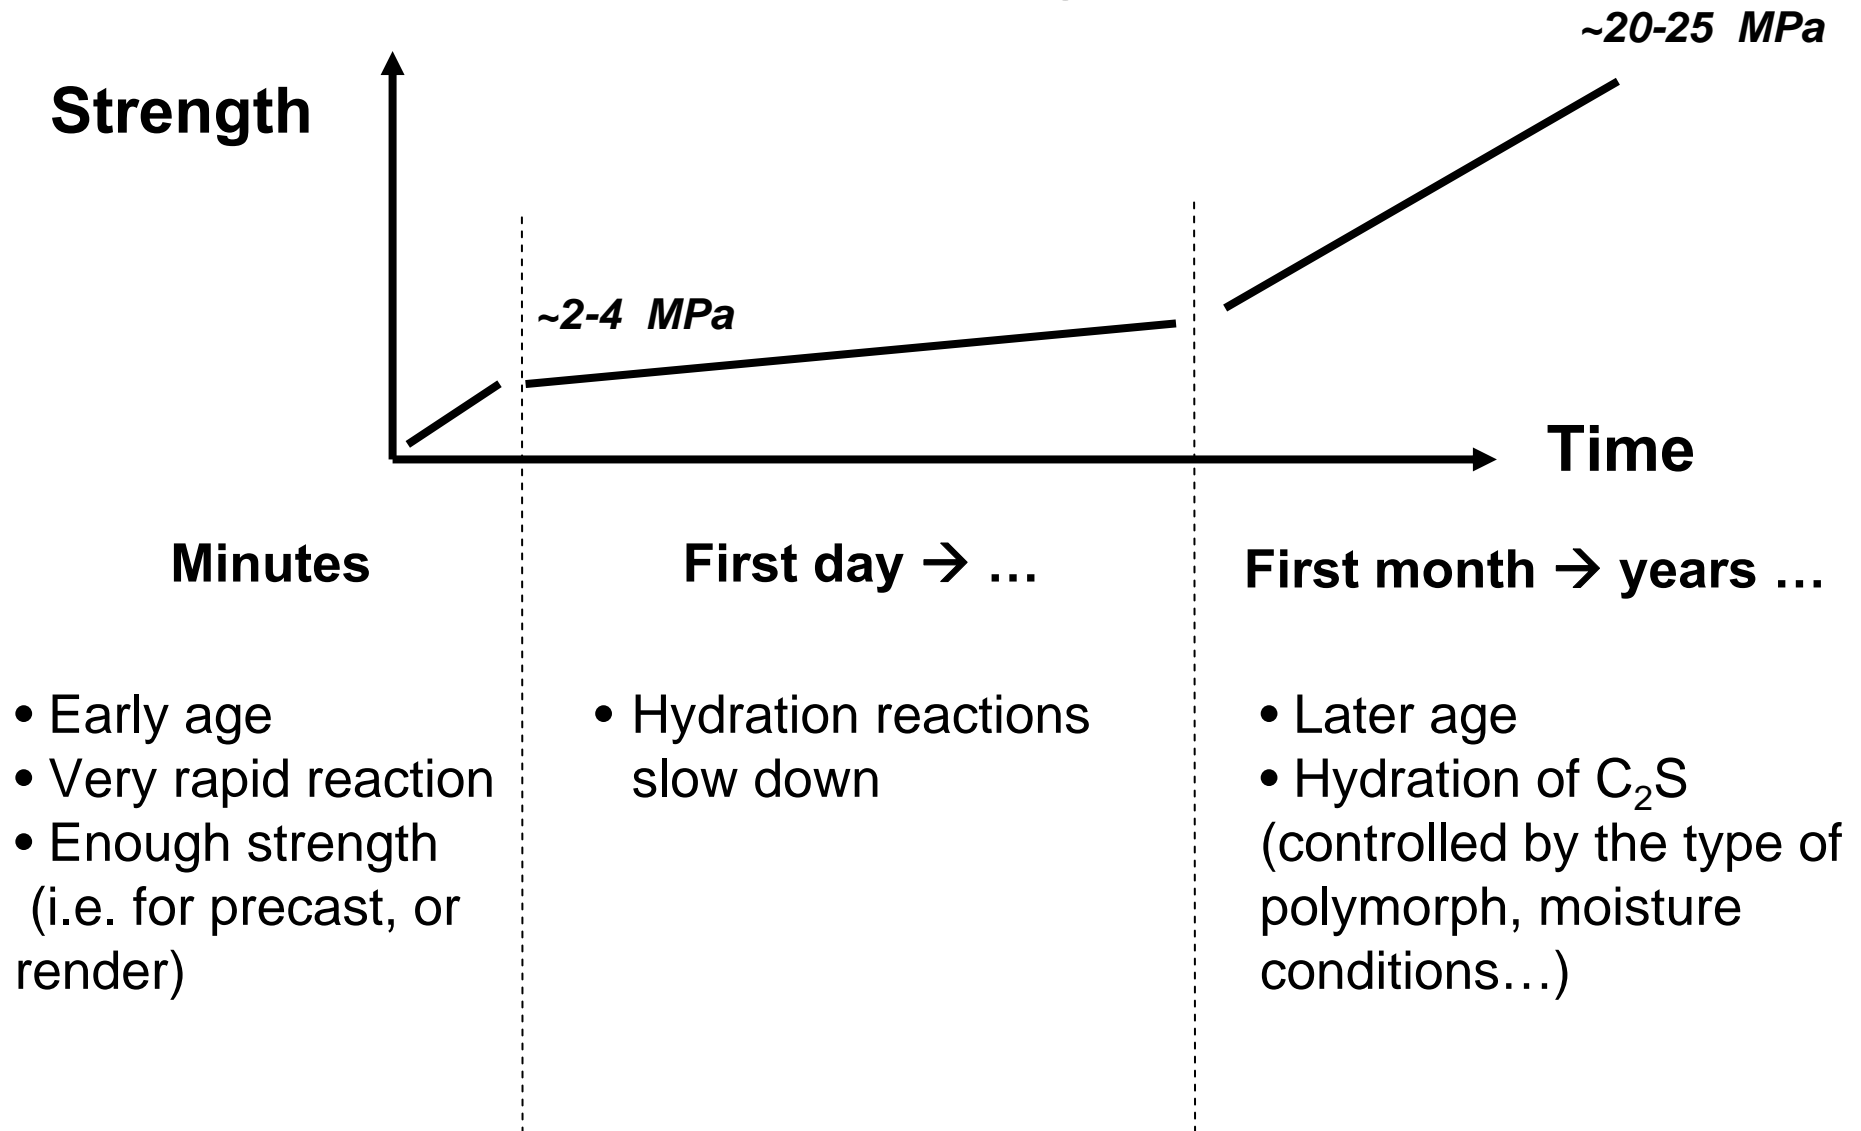

... hydrate ?

# 3/ Hydration of Roman cements

## Three main stages

- Early age
- Very rapid reaction
- Enough strength (i.e. for precast, or render)

- Hydration reactions slow down

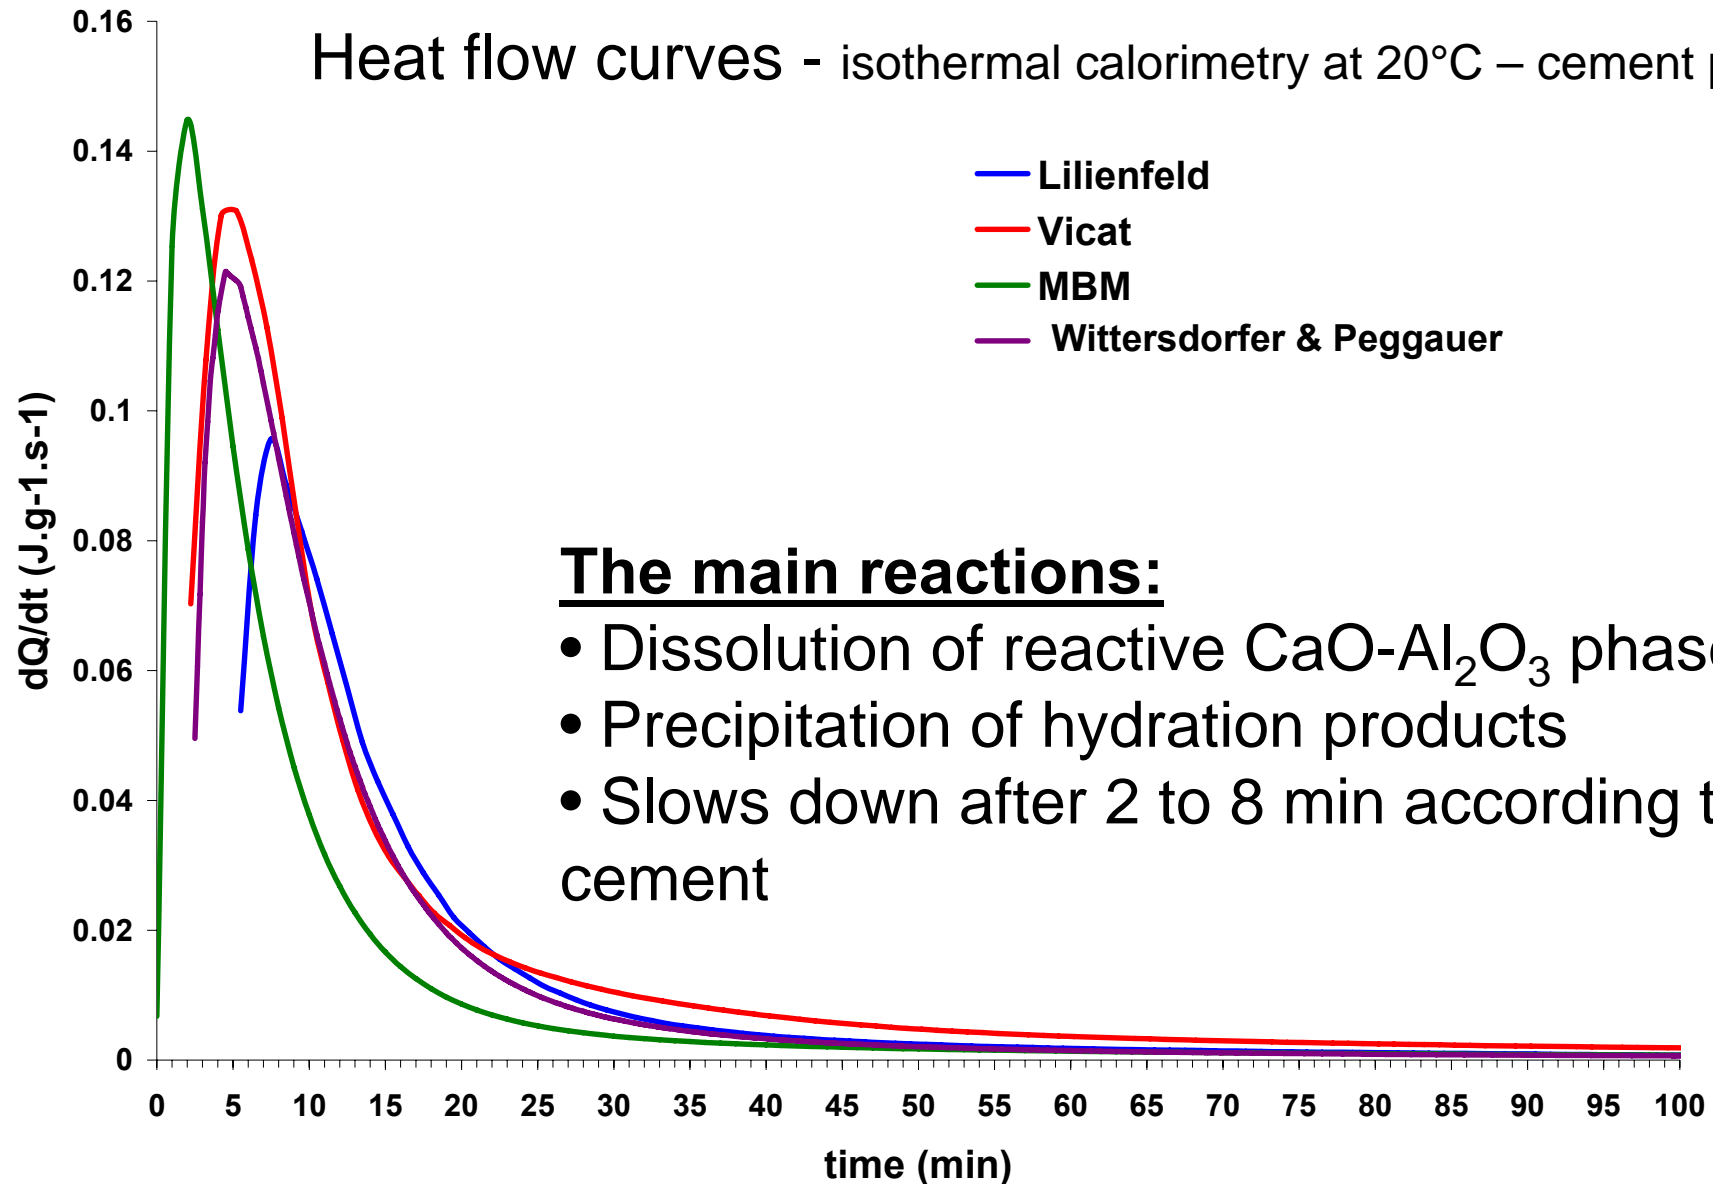

- Later age
- Hydration of C<sub>2</sub>S (controlled by the type of polymorph, moisture conditions...)

# 3/ Hydration of Roman cements

## Early age hydration

Heat flow curves - isothermal calorimetry at 20°C – cement paste

### The main reactions:

- Dissolution of reactive  $\text{CaO-Al}_2\text{O}_3$  phase
- Precipitation of hydration products
- Slows down after 2 to 8 min according to the cement

# 3/ Hydration of Roman cements

## Early age hydration products

In cements containing **sulfate and carbonate**  
(Vicat)

→ Assemblage typical to Vicat cement

# 3/ Hydration of Roman cements

## Early age hydration products

In cements containing **no sulfate but carbonate**  
(Lilienfeld, Wittersdorfer & Peggauer)

Phase containing **CO<sub>3</sub>** (solid solution)

6 7 8 9 10 11 12 13

°2θ

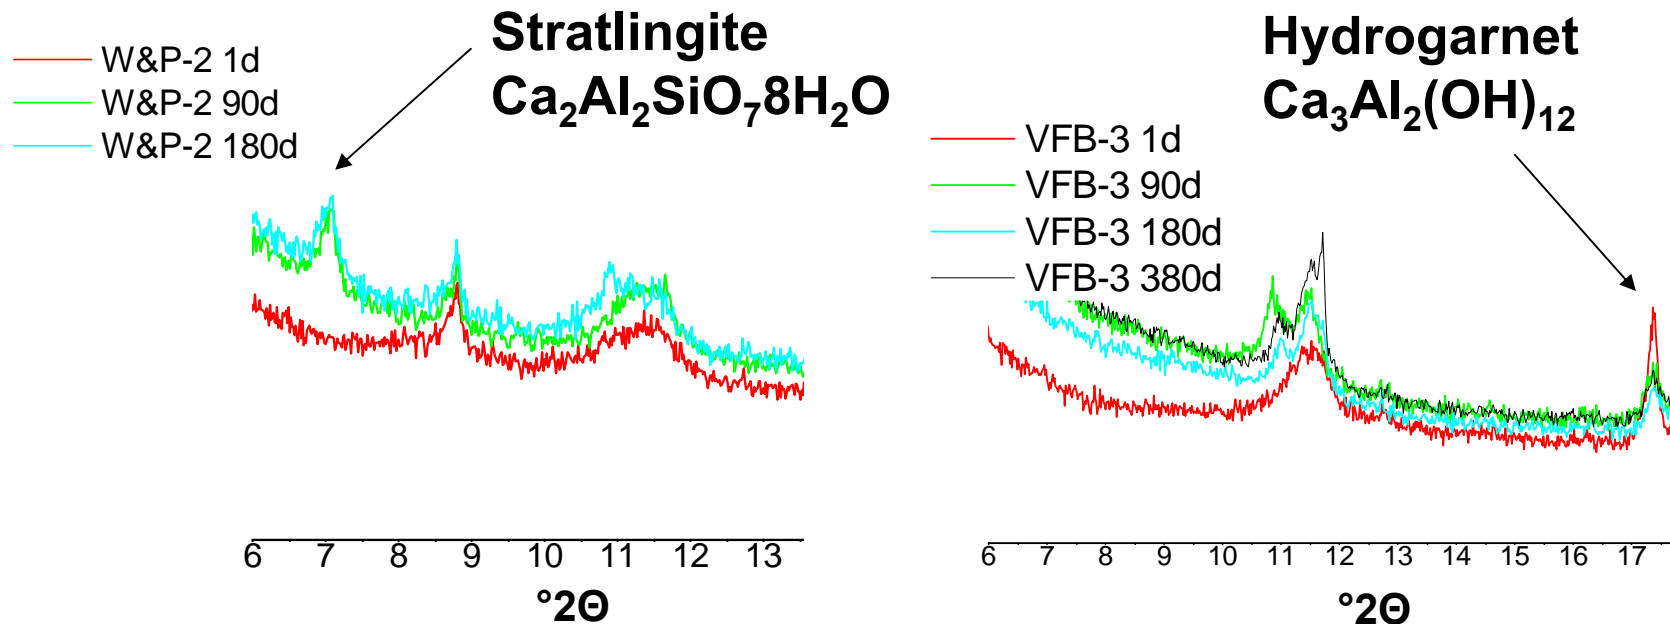

→ Usual phases in Roman Cements

# 3/ Hydration of Roman cements

## Early age hydration products

In cements containing **no sulfate nor carbonate**  
(one VFB and one prototype W&P cement)

Other phases than Hemi- and Monocarboaluminate are formed

→ Usual phases in other cementitious systems, but rarely reported in Roman Cements

# Concluding remarks (1/3)

- Roman cements are unique materials (cement chemistry and mortars properties)
- The mechanical and transport properties of mortars result from the rapid development of a complex microstructure
- Vicat remains a specific cement because contains  $C_3S$  and gypsum

## Concluding remarks (2/3)

- The nature of the first hydration products depends on the presence of carbonate and/or sulfate in the cement
- The assemblage made of  $\text{CaO-Al}_2\text{O}_3\text{-CO}_3\text{-H}_2\text{O}$  is identified in mostly all Rocare RCs
- Regardless of their nature, these first products are stable for several years

## Concluding remarks (3/3)

- Later,  $C_2S$  hydrate to fill the microstructure up after few days/weeks with other products (C-S-H, CH...) → strength increase
- But the relative reactivity of  $C_2S$  strongly depends on the type ( $\alpha'$  or  $\beta$ ) and the possible carbonation in the kiln, reducing their availability
